

Binary Tree Traversal Methods

- In a traversal of a binary tree, each element of the binary tree is **visited** exactly once.
- During the **visit** of an element, all action (make a clone, display, evaluate the operator, etc.) with respect to this element is taken.

Binary Tree Traversal Methods

- Preorder
- Inorder
- Postorder
- Level order

Preorder Traversal

```
public static void preOrder(BinaryTreeNode t)
{
    if (t != null)
    {
        visit(t);
        preOrder(t.leftChild);
        preOrder(t.rightChild);
    }
}
```

Preorder Example (visit = print)

a b c

```
public static void preOrder(BinaryTreeNode t)
{
    if (t != null)
    {
        visit(t);
        preOrder(t.leftChild);
        preOrder(t.rightChild);
    }
}
```

Preorder Example (visit = print)

a b d g h e i c f j

Preorder Of Expression Tree

$/ * + a b - c d + e f$

Gives prefix form of expression!

Inorder Traversal

```
public static void inOrder(BinaryTreeNode t)
{
    if (t != null)
    {
        inOrder(t.leftChild);
        visit(t);
        inOrder(t.rightChild);
    }
}
```

Inorder Example (visit = print)

b a c

Inorder Example (visit = print)

g d h b e i a f j c

Inorder By Projection (Squishing)

Inorder Of Expression Tree

Gives infix form of expression (sans parentheses)!

Postorder Traversal

```
public static void postOrder(BinaryTreeNode t)
{
    if (t != null)
    {
        postOrder(t.leftChild);
        postOrder(t.rightChild);
        visit(t);
    }
}
```

Postorder Example (visit = print)

b c a

Postorder Example (visit = print)

g h d i e b j f c a

Postorder Of Expression Tree

a b + c d - * e f + /

Gives postfix form of expression!

Traversal Applications

- Make a clone.
- Determine height.
- Determine number of nodes.

Level Order

Let **t** be the tree root.

```
while (t != null)
```

```
{
```

```
    visit t and put its children on a FIFO queue;
```

```
    remove a node from the FIFO queue and  
    call it t;
```

```
    // remove returns null when queue is empty
```

```
}
```

Level-Order Example (visit = print)

a b c d e f g h i j

Binary Tree Construction

- Suppose that the elements in a binary tree are distinct and a traversal sequence is given
- Can you construct the binary tree from which a given traversal sequence came?
- When a traversal sequence has more than one element, the binary tree is not uniquely defined.
- Therefore, the tree from which the sequence was obtained cannot be reconstructed uniquely.

Some Examples

preorder

= ab

inorder

= ab

postorder

= ab

level order

= ab

Binary Tree Construction

- Can you construct the binary tree, given two traversal sequences?
- Depends on which two sequences are given.

Preorder And Postorder

preorder = **ab**

postorder = **ba**

- Preorder and postorder do not uniquely define a binary tree.
- Nor do preorder and level order (same example).
- Nor do postorder and level order (same example).

Inorder And Preorder

- inorder = g d h b e i a f j c
- preorder = a b d g h e i c f j
- Scan the preorder left to right using the inorder to separate left and right subtrees.
- a is the root of the tree; gdhbei are in the left subtree; fjc are in the right subtree.

Inorder And Preorder

- preorder = a b d g h e i c f j
- b is the next root; gdh are in the left subtree; ei are in the right subtree.

inorder = g d h b e i a f j c

Inorder And Preorder

- preorder = a b d g h e i c f j
- d is the next root; g is in the left subtree; h is in the right subtree.

inorder = g d h b e i a f j c

Inorder And Postorder

- Scan postorder from right to left using inorder to separate left and right subtrees.
- inorder = g d h b e i a f j c
- postorder = g h d i e b j f c a
- Tree root is a; gdhbei are in left subtree; fjc are in right subtree.

Inorder And Level Order

- Scan level order from left to right using inorder to separate left and right subtrees.
- inorder = g d h b e i a f j c
- level order = a b c d e f g h i j
- Tree root is a; gdhbei are in left subtree; fjc are in right subtree.
