

# Deadlock Detection

- Allow system to enter deadlock state
- Detection algorithm
- Recovery scheme

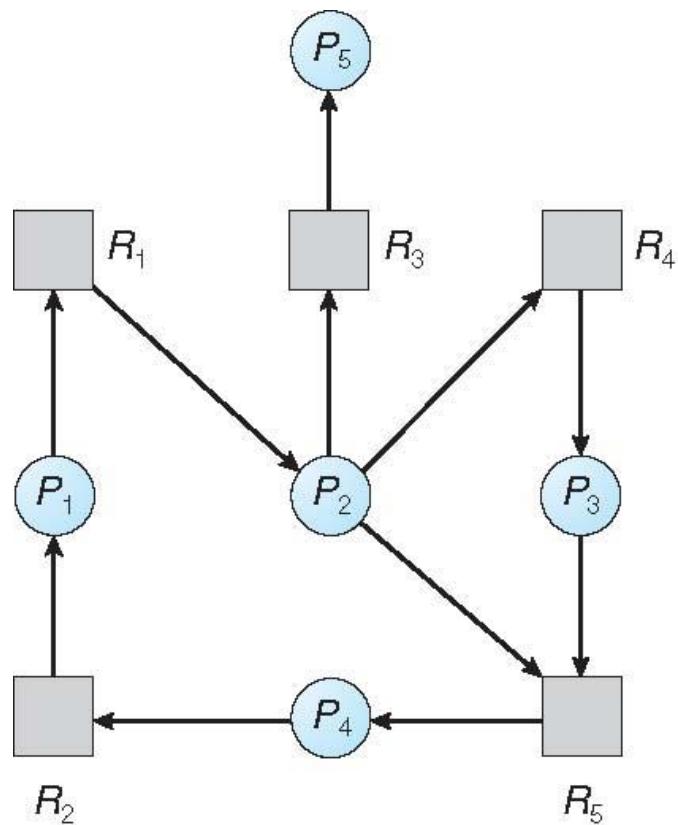

# Single Instance of Each Resource Type

- Maintain **wait-for** graph
  - Nodes are processes
  - $P_i \rightarrow P_j$  if  $P_i$  is waiting for  $P_j$
- Periodically invoke an algorithm that searches for a cycle in the graph. If there is a cycle, there exists a deadlock
- An algorithm to detect a cycle in a graph requires an order of  $n^2$  operations, where  $n$  is the number of vertices in the graph

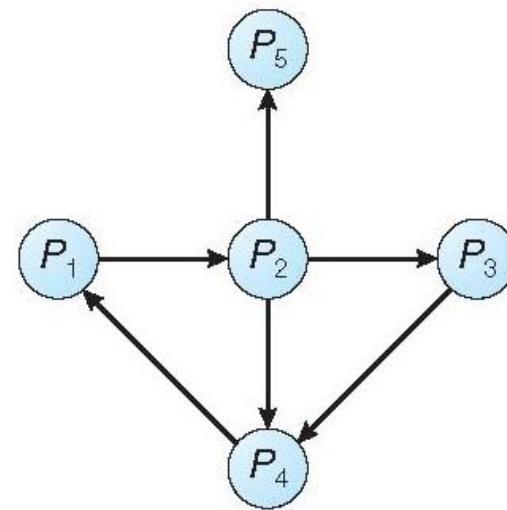

# Resource-Allocation Graph and Wait-for Graph

Resource-Allocation Graph

Corresponding wait-for graph

# Several Instances of a Resource Type

- **Available:** A vector of length  $m$  indicates the number of available resources of each type
- **Allocation:** An  $n \times m$  matrix defines the number of resources of each type currently allocated to each process
- **Request:** An  $n \times m$  matrix indicates the current request of each process. If  $\text{Request}[i][j] = k$ , then process  $P_i$  is requesting  $k$  more instances of resource type  $R_j$ .

# Detection Algorithm

---

1. Let **Work** and **Finish** be vectors of length **m** and **n**, respectively Initialize:
  - (a) **Work = Available**
  - (b) For  $i = 1, 2, \dots, n$ , if **Allocation<sub>i</sub>**  $\neq 0$ , then  
**Finish[i] = false**; otherwise, **Finish[i] = true**
2. Find an index **i** such that both:
  - (a) **Finish[i] == false**
  - (b) **Request<sub>i</sub> ≤ Work**If no such **i** exists, go to step 4

## Detection Algorithm (Cont.)

---

3.  $\text{Work} = \text{Work} + \text{Allocation}_i$ ,  
 $\text{Finish}[i] = \text{true}$   
go to step 2
4. If  $\text{Finish}[i] == \text{false}$ , for some  $i$ ,  $1 \leq i \leq n$ , then  
the system is in deadlock state. Moreover, if  
 $\text{Finish}[i] == \text{false}$ , then  $P_i$  is deadlocked

**Algorithm requires an order of  $O(m \times n^2)$  operations  
to detect whether the system is in deadlocked state**

# Example of Detection Algorithm

- Five processes  $P_0$  through  $P_4$ ; three resource types A (7 instances), B (2 instances), and C (6 instances)
- Snapshot at time  $T_0$ :

	<u>Allocation</u>			<u>Request</u>			<u>Available</u>		
	A	B	C	A	B	C	A	B	C
$P_0$	0	1	0	0	0	0	0	0	0
$P_1$	2	0	0	2	0	2			
$P_2$	3	0	3	0	0	0			
$P_3$	2	1	1	1	0	0			
$P_4$	0	0	2	0	0	2			

- Sequence  $\langle P_0, P_2, P_3, P_1, P_4 \rangle$  will result in  $Finish[i] = \text{true}$  for all  $i$

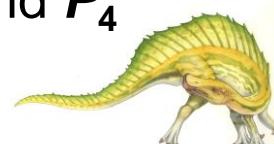

## Example (Cont.)

- $P_2$  requests an additional instance of type **C**

Request

	A	B	C
$P_0$	0	0	0
$P_1$	2	0	2
$P_2$	0	0	1
$P_3$	1	0	0
$P_4$	0	0	2

- State of system?
  - Can reclaim resources held by process  $P_0$ , but insufficient resources to fulfill other processes; requests
  - Deadlock exists, consisting of processes  $P_1$ ,  $P_2$ ,  $P_3$ , and  $P_4$

# Detection-Algorithm Usage

- When, and how often, to invoke depends on:
  - How often a deadlock is likely to occur?
  - How many processes will need to be rolled back?
    - ▶ one for each disjoint cycle
- If detection algorithm is invoked arbitrarily, there may be many cycles in the resource graph and so we would not be able to tell which of the many deadlocked processes “caused” the deadlock.

# Recovery from Deadlock: Process Termination

- Abort all deadlocked processes
- Abort one process at a time until the deadlock cycle is eliminated
- In which order should we choose to abort?
  1. Priority of the process
  2. How long process has computed, and how much longer to completion
  3. Resources the process has used
  4. Resources process needs to complete
  5. How many processes will need to be terminated
  6. Is process interactive or batch?

## Recovery from Deadlock: Resource Preemption

- **Selecting a victim** – minimize cost
- **Rollback** – return to some safe state, restart process for that state
- **Starvation** – same process may always be picked as victim, include number of rollback in cost factor

# Example of Banker' s Algorithm

- Consider the following snapshot of a system:
  - Snapshot at time  $T_0$ :

	<u>Allocation</u>	<u>Max</u>	<u>Available</u>
	A B C D	A B C D	A B C D
$P_0$	2 0 0 1	4 2 1 2	3 3 2 1
$P_1$	3 1 2 1	5 2 5 2	
$P_2$	2 1 0 3	2 3 1 6	
$P_3$	1 3 1 2	1 4 2 4	
$P_4$	1 4 3 2	3 6 6 5	

- Illustrate that the system is in Safe State.
- If a request from P1 arrives (1,1,0,0), can it be granted immediately?
- If a request from P4 arrives (0,0,2,0), can it be granted immediately?

# Example of Banker' s Algorithm

- Consider a system consisting of  $M$  resources of the same type being shared by  $N$  processes. A process can request or release only one resource at a time. Show that the system is deadlock free if the following two conditions hold:
  - The maximum need of each process is between one resource and  $M$  resources.
  - The sum of all maximum needs is less than  $M+N$ .

# Example of Banker's Algorithm

---

- A system using the Banker's algorithm for resource allocation contains  $n_1$  and  $n_2$  resource units of type R1 and R2 and three processes P1, P2 and P3. The available resources are (1,1). The following observations are made regarding the operation of the system:
  - If process P1 makes a (1,0) request followed by (0,1) request. The request (1,0) is granted but (0,1) is denied.
  - If instead, P1 request for (0,1), it is granted immediately.

Find a possible set of values for the current allocations and maximum resource requirements of the processes such that decision using the banker's algorithm will match the above observation.

# End of Chapter 7
